CARATSPACE · BY CARATSENSE

The CRM, documented

Every customer-facing capability of the CaratSpace platform — the nine ways an enquiry arrives, how the bot converses, how the AI assists without overstepping, how people work leads to won or lost, and how the business measures all of it — in one reference.

Prepared for Nibhana · 12 October 2026 · written against the current build, including the campaign-conversation round (PRs #40 / #42, pending merge)

Contents

1	How enquiries arrive — nine doors into one pipeline
2	Ad attribution & routing — knowing which ad, sending it to the right branch
3	The unified inbox — every conversation, with its complete trail
4	The WhatsApp bot — campaign conversations, walk-ins, and handoff to people
5	The AI assistant — scoring, drafting, and auto-send, each its own switch
6	Leads & pipeline — board, follow-ups, calling queue, fair assignment
7	Customers — identity, the 360° view, tags, merges, archiving
8	The showroom floor — the in-store app, visits, and check-ins
9	Feedback & reviews — happy customers get the review link, unhappy ones get a person
10	The response promise — first-reply SLA measurement and escalation
11	Outbound campaigns — audiences, approval, and the send that can be accounted for
12	Messaging rules — consent, the 24-hour window, templates, and sender routing
13	Reporting & dashboards — KPIs, the lead funnel, digests, and the audit trail
14	Roles, stores & honest limits — who sees what, and what the system refuses to pretend

1 How enquiries arrive

Nine doors, one pipeline. Every door runs the same intake sequence — resolve the customer, open the lead, schedule follow-ups, record the trail — and every door is idempotent, so a retry or a double-tap can never create the same lead twice.

Door	What happens
WhatsApp ad click (CTWA)	The customer taps a Meta ad and lands in WhatsApp. The ad is identified automatically (section 2) and a lead opens when a routing rule names the branch — a branch is never guessed.
Organic WhatsApp message	Becomes a conversation; a salesperson converts it to a lead with one button, naming the interest and branch. Deliberately not automatic — most messages aren't sales enquiries, and auto-leads would make every conversion rate meaningless.
QR poster in the store	A manager prints a branch QR (with expiry); a visitor scans and files their own enquiry. Anonymous, consent-required, throttled, honeypot-protected.
Website enquiry forms	Embeddable per-branch forms with origin control; phone or email required; submissions file straight into the branch.
Meta Lead Ads	A lead-form submission on Facebook/Instagram becomes a lead; the form's custom questions and answers are kept and shown on the lead. Fetching runs as a retried background job so Meta always gets a fast acknowledgement.
Phone / missed call	A telephony-provider notification creates the customer, the enquiry, the call record and a follow-up task. (Provider-neutral; not yet exercised against a live provider.)
Manual entry at the counter	Name (must contain letters), mandatory Indian mobile, interest, value, source, owner. Two SOP follow-ups are auto-scheduled at +7 and +30 days.
Bulk import	After a customer import, one command opens leads for the whole batch (up to 2,000 at a time).
Conversation → lead	The rep reading a thread presses "convert", names the interest, and the anonymous sender becomes a customer record — idempotent per conversation.

2 Ad attribution & routing

Knowing which ad

- **Automatic ad identification.** Meta attaches a referral to the first message of an ad click; CaratSpace reads the ad id and resolves its ad-set and campaign names via the Graph API — in the background, so a slow Meta call can never delay or duplicate the customer's message.
- **Instagram vs Facebook** is recorded per lead (never guessed — genuinely unknown stays "unknown" and is listable for audit), and the ad's card (headline, image) is shown on the exact message that brought the customer in.
- **First touch is permanent.** A second ad click later never rewrites where the customer originally came from — it is recorded as its own touch on its own message.
- **Evidence honesty.** Every attribution touch is labelled `measured` (a click id carried it in), `inferred` (a rule matched) or `declared` (a human picked it from a dropdown) — and the three are never merged. A lead with no source produces an explicit "unknown", not a default of "organic". Spend decisions rest on measured evidence; the customer panel shows the badge, not just the word "Instagram".
- **ROAS.** Meta ad spend and delivery metrics can be synced and joined to CRM leads; campaign rollups report revenue and lead counts under first-touch or last-touch models.

Routing to the right branch and person

- **Routing rules** match an arrival by exact ad (paste the ad's link — the id is parsed out of it), whole campaign by name, or ad-set by name. **The most specific match wins** — "Bandra Broadway" structurally beats

"Bandra", so overlapping showroom names can't misroute; priority only breaks genuine ties.

- A rule assigns the branch, optionally a named owner, and bot-vs-human handling — and carries that campaign's conversation (section 4). A rule pointing at a closed store, or at a person who can't open the inbox, degrades safely: the thread waits in the head-office queue rather than landing somewhere wrong.
- **Routing conflicts are reviewed, not auto-resolved.** If a later ad would move an already-owned thread, nothing moves — a conflict row records original vs proposed, and a manager decides: keep, accept, or manual. Resolved conflicts are kept as the record of that decision.
- **Fair assignment (round-robin).** A branch can opt into a rotation across its eligible salespeople for new inbound work; an explicitly named owner from an ad rule always wins.

3 The unified inbox

- **One list, every channel.** WhatsApp, Instagram, email, phone, SMS, website chat — newest activity first, with a real preview of the last message, the customer's lead tags, assignee, branch, message count and the ad that brought them in.
- **Queues with honest counts** — Inbox, Assigned to me, Unassigned, With assistant, Needs review, Unknown sender, Closed, and a head-office-only "Non-ad" queue. Counts are computed server-side under the same visibility rules as the list.
- **Who sees what:** a salesperson sees only threads assigned to them; a store manager their stores; head office everything plus the centrally-unassigned queue. Filters can narrow, never widen.
- **Reply in place, signed.** A reply goes out on the customer's channel prefixed with the agent's name (WhatsApp bold) — the stored transcript equals exactly what the customer received. Replying takes the thread over: handling flips to human and the bot is locked out permanently.
- **Honest delivery states.** The composer returns *queued* or *saved* — never "sent" — with the verbatim reason when policy blocks it ("outside the 24-hour window", "customer opted out"). Per-message ticks show Read / Delivered / Sent / Not delivered (with the error) / Queued.
- **Customer photos** are stored privately and served only to people who can open the thread — bytes, never a public link.
- **Assign & route** (manager action): change branch, owner and handling in one validated step — a thread can never be owned by someone who doesn't work at its branch. The new owner is notified; if no owner, every manager at the destination branch is.
- **Thread tools:** click-to-call, close/reopen/snooze, attach a catalogue item or quotation, record product interest, add a follow-up, emoji picker, search across name/phone/preview. A closed thread reopens by itself when the customer writes again.
- **One customer, one thread.** Threads key on the customer's number, so a customer who writes to two of the business's numbers lands in a single conversation — and replies leave from the number the customer last wrote to, where their 24-hour window is open.

4 The WhatsApp bot

Campaign conversations — configured per ad, on one screen

- Each campaign entry (Bot Script page) carries: **the first reply, sent exactly as written** (it answers the ad's own promise and is never reworded); up to **5 guiding questions**, each optionally with **choices** woven into a natural sentence ("What style are you looking for — studs, jhumkas, drops?") — never buttons, never menus; the **brief** the assistant may answer from; and **house rules**.
- **AI replies On/Off per campaign.** On: free-text follow-ups are answered from the brief. Off: the opener still sends, and the very next customer message goes to a colleague with the campaign named.

- Applies to **a whole campaign (type its name)** or **one specific ad (paste its link)** — so different ads under one campaign can carry different conversations.
- Retry-safe: "has the opener gone?" is answered by counting the thread's outbound bot messages, not a flag — a replayed webhook can't double-send it.

Walk-ins and the legacy questionnaire

- **The walk-in conversation** is the same anatomy for customers who arrive from no ad: opener, questions with choices, brief, AI toggle. On, it replaces the old questionnaire; off, nothing changes. A matching campaign always wins over it.
- **The legacy questionnaire** (the original 5-step flow: looking-for → budget → timeline → call preference → call time) still runs for tenants who enable nothing. Its wording is tenant-editable per step; its stored values are not (renaming a value would orphan every recorded answer). It never re-asks what a lead form already answered, gives up politely after two re-prompts instead of trapping the customer, and remembers finished enquiries for 7 days so nobody is re-interrogated.

Guardrails that are always on

- **"Talk to a person"** is detected deterministically and hands off instantly — never dependent on a model. **Complaints, legal threats and opt-outs** are screened before any AI sees them (word-boundary matching: "sue" never fires on "issue"; "stop" only as a whole message).
- **STOP always wins.** Opt-out is checked first on every message, even mid-question, even from a never-seen number — and is honoured permanently as a consent event.
- **A photo goes to a person.** Nothing in the system can price a photo, so a media message skips the script and lands with a human, thread attached.
- **Handoffs land with a named person** — the branch's store manager (stable, oldest account first), with the qualification summary as the opening message. The customer sees one continuous chat; no visible transfer. If no branch is known, the thread parks in the head-office queue rather than guessing.
- **Bot silence is deliberate.** The bot speaks only on threads that began with an ad click or where it is already mid-conversation; a stranger texting an internal staff line hears nothing (a reply would confirm the number is live).

The two lines

- **Customer line** — ads land here, the bot answers everyone as a customer. **Internal staff line** — linked staff file reports and message head office; strangers get silence. Staff link their own handset by texting a one-time code; managers can issue, list and revoke links, and an onboarding roster shows who still has no handset linked.

5 The AI assistant — three separate switches

> **Design rule.** One "AI enabled" toggle would mean the switch that turns on scoring is the same switch that starts messaging customers. So there are three: **Qualification** (score & summarise, sends nothing — default ON) · **Draft** (compose for human approval — default OFF) · **Auto-send** (deliver unaided — default OFF).

Lead qualification (scoring)

- **The model never decides the score.** AI only detects which of the tenant's own signals appear (with the matched phrase as evidence); the score is arithmetic over the tenant's weights and bands. It therefore works with **no AI provider at all** (keyword mode), every score is defensible, and weights can be negative ("asked for a refund" pushes down).

- Policy is tenant-owned: signals, score bands with recommended actions, confidence threshold, escalation score. A hot score moves a bot thread to a person while the customer is still typing. New messages trigger a debounced re-score (four quick messages = one assessment).
- Every assessment is a **new record, never an overwrite** — the history of what the business was told, when it acted, is preserved. A manager can override with their own 0–100 score, **reason mandatory**.
- The intent panel shows only measured figures — no defaulted "65 / warm / 0.82" ever appears.

Drafts with provenance, reviewed by humans

- A confident draft is stored with its provider, model, confidence, latency and the **named source documents** it drew from. The reviewer approves (optionally after editing) or rejects; approval yields *queued*, never "sent". Machine accounts can never approve a customer message.
- **No knowledge, no answer:** if retrieval finds nothing in the tenant's uploaded documents, the assistant refuses and hands off — "it only says what your documents say" is enforced, not just instructed.

Auto-send, caged

- Requires: the switch re-read live immediately before sending, confidence ≥ 0.85 (vs 0.55 for a draft — the gap is deliberate), a stricter screen, a known customer with consent, a branch that owns the reply — then the identical consent/window/template path a human's message takes.
- Daily cap (default 200) and a circuit breaker (5 consecutive provider failures → 15-minute cool-off). A policy refusal (24-hour window) never trips the breaker.

6 Leads & pipeline

- **Board and table.** Kanban by stage with drag-to-move, or a dense sortable table; facets Open/Won/Lost; filters by search, tags, source, date. Salespeople see their own leads; KPI bar and Excel export are manager-level.
- **Hot / warm / cold** is computed deterministically (recent activity, imminent follow-up, upcoming birthday/anniversary) — no AI required, same answer every time.
- **Lead detail:** log activities (note / call / visit / WhatsApp — logging sends nothing), add follow-ups, move stage, close won/lost (lost requires a reason; "order placed" closes as won).
- **Tags:** tenant-defined coloured labels (create/rename at manager level, apply at salesperson level), filter board and inbox by them. Tags are retired, never deleted — a used tag is part of the record.
- **Follow-up engine:** SOP follow-ups at +7/+30 days on every new lead; a Reminders page grouped Overdue / Today / Upcoming; tenant-set default reminder time ("you'll be reminded at 10:00"), resolved in each branch's own timezone; reminder notifications fire every minute.
- **Calling workspace:** every follow-up owed, oldest first, with the customer's history on one screen before dialling; outcome logging; headline counts that are true aggregates, not page counts. Phone numbers are masked (••••1234) except for managers and the task's own assignee.
- **Lead ageing / SLA buckets:** fresh / due-soon / breached / untouched with tenant-owned hour thresholds per stage, computed in store-local time.
- **Saved segments:** bounded, named lead queries with a real-count preview (manager-level — previews return customer names).
- **Excel export** (manager-level): pre-flight row count, refuses >50,000 rows with the real number rather than truncating silently; audit-logged.
- **Configurable pipeline:** rename/reorder/add/retire stages; defaults Inquiry (20%) → Quotation (50%) → Order placed (100%, won). Custom stages map back to system stages so every existing report keeps working.

7 Customers

- **"Who is this?"** — type a number at the counter: an exact match answers, an unknown number says so (never "nearest name"), and a colleague's customer answers *restricted* — "looked after by a colleague, ask your manager" — revealing nothing else.
- **Identity is exact or nothing.** Matching is byte-exact on normalised contact values — no fuzzy name merging ("R. Sharma" and "Rahul Sharma" are very often two people). A collision raises a **merge review** for a human; nothing is reassigned automatically.
- **Merging is plan-approved:** head office reads an exact plan of what the merge will do, and executes exactly that plan (hash-verified, so a stale plan can't be approved).
- **Customer 360:** contact points (phone/email/WhatsApp/Instagram), leads, conversations, visits, product interactions, quotes, sales, payments, returns, follow-ups and the timeline — with totals **computed live from rows** (never a cached figure that a voided sale forgot to update) and the scope stated in words ("totals cover only your stores").
- **Timeline & notes:** a per-customer event feed plus notes that include notes left on any of their leads — the whole picture in one list.
- **Product interest:** record viewed / shown / tried / shortlisted / rejected / purchased by item code; an unrecognised code is still recorded as text.
- **Directory & archive:** paged searchable directory with Excel export; archiving removes a contact from working lists and campaigns while keeping history and consent (so they are never messaged again by accident); a separate restore screen; deliberately no combined active+archived list.

8 The showroom floor

- **The in-store app** — a mobile-first screen for a salesperson standing with a customer: partial-match search (last three digits of a phone work), customer profile, barcode scan (safe to scan twice — it's a read), tabs for Leads / Visits / Today.
- **Recognition travels; enquiries don't.** A chain customer who bought in Surat is recognised in Mumbai, but another branch's open enquiries stay with that branch.
- **Record a visit:** who was served, purpose, outcome, notes, a counter photo, and up to 20 item enquiries each with converted/quantity/drop-off reason. The staff name comes from the account, never the request; a photo failure never blocks the visit.
- **Branch day:** today's figures (each its own true aggregate) and the visit feed for any branch day, in the branch's own timezone.
- **Check-ins & footfall:** log walk-ins with purpose (Bridal, Gold Coin & Investment, Repair, Quote follow-up, Browsing, Gold Scheme), assign to a rep, check out, export the walk-in log to Excel. Times are store-local (a 10:30 walk-in reads 10:30, not 05:00 UTC).

9 Feedback & reviews

- **The rule the module exists for:** a happy rating may be offered the branch's public review link; an unhappy one is routed to a person and **never** shown that link. Thresholds are tenant-set and must not overlap; whether a review link was offered is permanently recorded.
- **One review link per branch** (a Google profile is per-location — a customer who visited Nashik must not be sent to review Pune), https-only.
- **The ask:** the person who served the customer sends one question; delivery goes through the same consent/window path as every message. The customer answers a rating + comment on an unguessable public page.

- **Automatic after-visit ask:** N days after a walk-in that ended without a follow-up, the customer is asked how it went — skipped when a person is already coming back to them. If WhatsApp can't deliver (no template, no link), it becomes a task for the person who served them — never falsely recorded as sent. Opt-outs cancel it outright.
- **Summary:** average, distribution and individual responses (manager-level); "No answers yet" rather than a zero-star average.

10 The response promise (first-reply SLA)

- Head office sets the promise (e.g. **5 minutes**); off by default until a number is chosen. A clock opens on every inbound customer message.
- **What counts as an answer:** a person's reply or a human-approved AI reply that actually sent. Not an automatic acknowledgement (the system talking to itself), not a failed send.
- **On breach, exactly once:** an urgent "Reply overdue" task in the calling queue (due in the branch's own today), and a notification to the assignee — or to the branch's managers when nobody is assigned or the assignee can't open the inbox, with the title saying which. Escalation after N more minutes informs the managers, deliberately excluding the person already alerted.
- **The SLA board:** Missed / Waiting / In time with per-thread clocks; swept every minute, plus a manual sweep button.

11 Outbound campaigns (bulk messaging)

- **Audiences** are built from a bounded rule tree (customer fields, lead stage/source, spend, intent score, consent, birthdays/anniversaries, custom attributes — 25 conditions max), previewed with a true count and a 25-row sample. Hand-picked lists travel the identical safety path.
- **Lifecycle with real approval:** draft → submit → **approve (head office / area manager only)** → expand → send. **Approval freezes the audience** — editing the segment afterwards cannot change who an approved campaign reaches; the approver's number still means something at send time.
- **Caps and chunks:** 50,000 recipients max per campaign; sends process in chunks of 100 with visible progress; cancel marks recipients first so a running send finds nothing left.
- **Accountable recipients:** every excluded person carries a human-readable reason — opted out, consent required, archived, template refused. Phone numbers in campaign reports are masked to the last four digits.
- **The wizard orders audience before message** — the person writing the copy already knows how many people will read it. WhatsApp only today; the API shape is ready for SMS/RCS/email but the service refuses them until a live provider exists.

12 Messaging rules (consent, window, templates, senders)

- **Consent is an event, not a checkbox:** grants and revocations are stored as history; the current state is whichever is newest. An opt-out from a stranger still sticks. The screen shows the history, per channel and purpose (service vs marketing).
- **One gate for every send:** a single policy decides free-text vs template (24-hour customer-care window), refuses with a named reason (not connected / consent required / opted out / template required) — and every path (inbox reply, AI reply, campaign, feedback ask, staff digest) goes through it. No exceptions to skip the policy.
- **Templates:** write, submit to Meta, and sync approval status hourly. A template is unsendable until Meta says APPROVED — submission alone never arms the send button.

- **Outbox:** queued/failed sends visible with sweep and per-message retry; delivery receipts; dead-lettering. Every outbound state in the product (queued/sent/delivered/failed) is owned by the transport, so nothing can claim "sent" that wasn't.
- **Per-branch sender routing:** head office maps which WhatsApp number each branch sends from (one sender per branch; a number may serve several branches). A customer who wrote to the Surat shop is answered from the Surat number — and with several numbers connected, an unrouted send is refused rather than leaving as the wrong branch.

13 Reporting & dashboards

- **Omnichannel KPI bar** (30/90/365-day windows): leads, visits, enquiries, intent-band distribution, channel rollups (paid social / organic social / messaging). Three rules: every number is its own true aggregate; a count nobody can produce is *null*, never a zero that reads like a failing campaign; the vocabulary is the tenant's own.
- **Lead funnel on the main dashboard:** came vs converted, day by day (a lead that arrives Monday and converts Thursday belongs to both days, in different series); Today / 7 / 30 / 90 / 365 periods.
- **Management view:** cross-branch leads (by source, store, owner, stage), engagement (threads awaiting reply, SLA met/breached), the floor, quotes and feedback — with measured ad attribution reported separately from declared sources, and zero-vs-absent preserved ("a branch with no leads at all is a different Tuesday").
- **Staff morning digest:** each person's own due and overdue follow-ups — in-app always (the reliable channel), WhatsApp optionally via an approved template, with every skip reason recorded. Sent at the tenant's chosen hour in each store's own timezone.
- **DSR evening digest** to head office on the internal WhatsApp line once stores file; **scheduled reports** that send themselves with last-run outcomes shown.
- **The audit trail viewer:** every configuration change and sensitive action — rules edited, policies changed, campaigns approved, exports taken, customers merged — with who, when and a human-readable summary (50+ distinct CRM audit event types).

14 Roles, stores & honest limits

The role ladder

`salesperson` → `store manager` → `head office`. Backend permissions are a floor, re-checked server-side — a hidden button is a courtesy, the API check is the control. Machine accounts (sync tokens, agents) are additionally barred from human-only acts like approving an AI draft or recording consent.

Multi-store rules, consolidated

- Salespeople see assigned-to-me; managers their stores; head office everything plus the central unassigned queue. Filters narrow, never widen.
- The customer record is recognised chain-wide; their *history* is scoped, and narrower totals carry a visible scope note.
- Every store-naming write requires an active, trading store; stale rules and stale number mappings degrade to "unrouted + warning", never a silent wrong branch.
- All times — ageing, reminders, digests, SLA due dates, check-ins — resolve in each branch's own timezone, not the server clock.
- Tenant isolation everywhere: inbound messages have no "only one org, use it" fallback; identity keys, media reads and number ownership are all organisation-scoped.

What it deliberately does not pretend (current limits)

- Inbox **Starred** and **Snoozed** pills are per-browser only today (not yet saved to the server); **Unread** and **Follow Up** tabs currently show the same set as Inbox.
- **Auto-call on SLA breach** is wired but dials nothing yet — every blocked attempt logs its reason.
- **Telephony intake** is built provider-neutral but not yet exercised against a live provider.
- Bulk campaigns are **WhatsApp-only** until an SMS/email provider is connected — the service refuses the others rather than pretending.
- An ordinary WhatsApp message does **not** auto-create a lead — a person converts it, or an ad rule routes it. That is a design decision, not a gap: auto-leads would drown the pipeline and corrupt every conversion rate.

> **Field limits worth knowing.** 5 questions per conversation × 300 chars, 6 choices × 60; first reply 1,200; assistant brief 5,000; house rules 2,000; 60 tags per tenant, 30 per lead; segments 25 conditions; exports 50,000 rows; audiences 50,000 recipients; auto-send 200/day default. Over-length content is refused on save with the real number — never silently trimmed.
